# Math 213 - Exam II Review

Peter A. Perry

University of Kentucky

October 16, 2019

# Reminders

- Exam II takes place Tonight, October 16, 5:00-7:00 PM

# Unit II: Functions of Several Variables

## 13.3-4 Lecture 11: Velocity and Acceleration

### 14.1 Lecture 12: Functions of Several Variables

### 14.3 Lecture 13: Partial Derivatives

### 14.4 Lecture 14: Linear Approximation

### 14.5 Lecture 15: Chain Rule, Implicit Differentiation

### 14.6 Lecture 16: Directional Derivatives and the Gradient

### 14.7 Lecture 17: Maximum and Minimum Values, I

### 14.7 Lecture 18: Maximum and Minimum Values, II

### 14.8 Lecture 19: Lagrange Multipliers

### 15.1 Double Integrals

### 15.2 Double Integrals over General Regions

## Exam II Review

# Learning Goals

- Find out how to ace Exam II

## Acknowledgement:

Most of the sample problems in this lecture were taken from [Paul's Online Notes](#) at Lamar University. You can find solutions to these problems in the [Calculus III notes](#) there.

# Overview

- Arc length, velocity, acceleration
- Partial derivatives, chain rule
- Linear Approximation
- Directional derivatives, gradient
- Second derivative test for local extrema
- Closed interval method for global maxima and minima on a closed, bounded set
- Lagrange Multiplier Method
- Double integrals and Iterated Integrals (Section 15.1 *only*)

# Arc Length, Velocity, Acceleration

If  $\mathbf{r}(t)$  is a vector function:

- $\mathbf{r}'(t)$  is the tangent vector to the space curve at the point  $\mathbf{r}(t)$
- $\mathbf{r}''(t)$  is the acceleration of the particle at time  $t$
- $|\mathbf{r}'(t)|$  is the speed of a particle moving along the space curve at time  $t$

The *arc length* of a space curve  $\mathbf{r}(t)$ ,  $a \leq t \leq b$  is

$$L = \int_a^b |\mathbf{r}'(t)| dt.$$

# By Popular Demand

A ball is thrown at  $60^\circ$  with a velocity of 20m/sec to clear a wall 2m high. How far away is the wall?

# The Chain Rule

- 1 Find  $dz/dt$  if  $z = 4x^2 + 3y^2$ ,  $x(t) = \sin(t)$ ,  $y(t) = \cos(t)$ .
- 2 Suppose that  $z = f(x, y) = 3x^2 - 2xy + y^2$ ,  $x = 3u + 2v$ ,  $y = 4u - v$ . Find  $\partial z/\partial u$  and  $\partial z/\partial v$ .
- 3 The equation  $x^2 + y^3 + xyz = 1$  defines  $z$  implicitly as a function of  $x$  and  $y$ . Find  $\partial z/\partial y$  in terms of  $x$ ,  $y$ , and  $z$ .

# Tangent Planes, Linear Approximation

Find the tangent plane to the graph of  $f(x, y) = x^2 + 4y^2$  at the point  $(2, 1, 8)$ .

Using the linear approximation, estimate  $f(0.1, 1.9)$  if  $f(x, y) = \sqrt{8 - x^2 - y^2}$ .

# The Gradient

## How to Compute It

If  $f$  is a function of *two variables*,  $\nabla f(x, y) = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right\rangle$

If  $f$  is a function of *three variables*,  $\nabla f(x, y, z) = \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z} \right\rangle$

## What it Means

The magnitude of  $\nabla f(a, b)$  (or  $\nabla f(a, b, c)$ ) is the maximum rate of change of  $f$  at  $(a, b)$  (or  $(a, b, c)$ )

The direction of  $\nabla f(a, b)$  (or  $\nabla f(a, b, c)$ ) is the direction of the maximum rate of change of  $f$  at  $(a, b)$  (or  $(a, b, c)$ )

# The Gradient

## What it Does

The directional derivative of  $f(x, y)$  at  $(a, b)$  in the direction  $\mathbf{u}$  (where  $\mathbf{u}$  is a *unit vector* is

$$D_{\mathbf{u}}f(a, b) = \nabla f(a, b) \cdot \mathbf{u}.$$

The gradient of a function of two variables is perpendicular to level curves of  $f$

The gradient of a function of three variables is perpendicular to level surfaces of  $f$

- 1 Find the maximum rate of change of  $f(x, y) = 3x^2 + 4y^2$  at  $(1, 2)$ , and find the direction  $\mathbf{u}$  of that maximum rate of change
- 2 Find the directional derivative of  $f(x, y) = e^{xy}$  at the point  $(1, 2)$  in the direction  $\mathbf{u} = \left\langle \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}} \right\rangle$
- 3 Find the equation of the tangent plane to the level surface of  $x^2 + 4y^2 + 9z^2 = 17$  at the point  $(2, 1, 1)$ .

## Second Derivative Test

- Local extrema occur at critical points, i.e., points  $(a, b)$  where  $f_x(a, b) = f_y(a, b) = 0$
- A critical point corresponds to a local maximum or minimum if

$$D = f_{xx}(a, b)f_{yy}(a, b) - f_{xy}(a, b)^2$$

is positive

- A critical point with  $D > 0$  is a local minimum if  $f_{xx}(a, b) > 0$ , and a local maximum if  $f_{xx}(a, b) < 0$
- 1 Find the local maxima and minima for the function  $f(x, y) = 3x^2y + y^3 - 3x^2 - 3y^2 + 2$
  - 2 Find the point on the plane  $4x - 2y + z = 1$  closest to the point  $(-2, -1, 5)$

# Closed Set Method

To find the maximum and minimum of a function  $f$  on a bounded closed set  $D$ :

- 1 Find all local maxima and minima of  $f$  in  $D$  using the second derivative test
- 2 Find the maximum and minimum of  $f$  on the boundary of  $D$  using the Closed Interval Method from Calculus I

Find the absolute maximum and minimum of  $f(x, y) = 2x^2 - y^2 + 6y$  in the region  $D$  with  $x^2 + y^2 \leq 16$ .

# Lagrange Multipliers

A constrained optimization problem consists of:

- An *objective function*  $f$  to be maximized or minimized
- One or more *constraint equations* which must also be satisfied

For a constrained optimization problem with one constraint, two variables, solve:

$$\begin{aligned}\nabla f &= \lambda \nabla g && \text{(two equations)} \\ g(x, y) &= c && \text{(one equation)}\end{aligned}$$

For two constraints, three variables, solve:

$$\begin{aligned}\nabla f &= \lambda \nabla g_1 + \mu \nabla g_2 && \text{(three equations)} \\ g_1(x, y, z) &= c_1 && \text{(one equation)} \\ g_2(x, y, z) &= c_2 && \text{(one equation)}\end{aligned}$$

# Lagrange Multipliers

- 1 Find the maximum and minimum of the function  $f(x, y) = 5x - 3y$  on the circle  $x^2 + y^2 = 136$
  
- 2 Find the maximum of  $f(x, y, z) = 4y - 2z$  subject to the constraints  $2x - y - z = 2$  and  $x^2 + y^2 = 1$

# Double Integrals

The *double integral* of a function  $f$  over a rectangle  $R = [a, b] \times [c, d]$  is denoted

$$\iint_R f(x, y) dA.$$

To compute it, we can compute the iterated integral

$$\int_a^b \left( \int_c^d f(x, y) dy \right) dx$$

or the iterated integral

$$\int_c^d \left( \int_a^b f(x, y) dx \right) dy.$$

- 1 Find  $\iint_R 6xy^2 dA$  if  $R = [2, 4] \times [1, 2]$
- 2 Find  $\iint_R xe^{xy} dA$  if  $R = [-1, 2] \times [0, 1]$
